TheCommander

Verified workbench on Vultr

A personal engineering assistant that carries context from a question to a reviewable plan, bounded execution and a verifiable receipt.

From an answer to evidence

A workflow people can inspect

Plan → inspect authority → execute in isolation → verify output → retain the receipt. Code runs offline; browser changes require an exact, expiring human approval.

One control plane

FastAPI · React · PostgreSQL

The durable worker preserves context and schedules. A separate trusted runner dispatches disposable code/browser containers. Scoped connections keep provider credentials outside execution jobs.

Boundaries are testable

Confinement before execution

Read-only roots, dropped capabilities, unprivileged users, resource limits and container destruction. Chromium retains its own sandbox; an isolated gateway restricts browser destinations.

What the evidence says

Passing CI; explicit release gates

176 Python tests, 11 browser scenarios and 90.52% CI coverage. Fresh Nebius and Tavily calls passed. Vultr authentication, SSH trust, HTTPS deployment and human-approved live browser effects remain blocked.

Next: demonstrate the real system

One task, one receipt

Record a real Vultr-generated calculation, denied network/host access, exact browser approval and a verified result. Publish matching source, judge access and operational evidence after the remaining gates pass.
